**Preventing Falls in the Geriatric Population**

Aimee Lee, MD; Kuo-Wei Lee, MD; Peter Khang, MD, MPH, FAAFP

Introduction

The word “fall” does not usually strike fear in the hearts of most people. But it should. Falls are all too common in the geriatric population, and they have devastating consequences. They are the leading cause of injury and death by injury in adults over the age of 65 years.¹ One of 5 community-dwelling older adults falls each year, with 24% of those who fall sustaining serious injuries and 6% sustaining fractures.² In the year 2000, falls cost the US health care system more than $19 billion, a number that is expected to increase to $54.9 billion by 2020.³ A person who falls may subsequently experience pain, hospitalization, surgical intervention, admission to a nursing home, decreased overall functional ability, poorer quality of life, or a fear of falling.

Fear of Falling

Fear of falling is a defined geriatric syndrome that may contribute to further functional decline in an already frail patient. When people experience something unpleasant, their natural response is an aversion to that experience. People may begin to limit their activities after a fall or as they become weaker and less agile with increasing age. This leads to a more sedentary lifestyle and physical atrophy, which further predisposes them to falls. Successful encouragement to maintain or increase physical activity may promote the ability to avoid falling or to catch oneself before a fall.

Why Patients Fall

Normal gait and balance requires freely moving joints; muscles contracting at the right time with the appropriate strength; and accurate visual, vibratory, and proprioceptive input. As patients age, they may experience stiffened joints, decreased muscle strength, and impaired neurologic feedback. These changes, in combination with other risk factors, increase the likelihood of falls. The strongest independent risk factors for falls are previous falls, weakness, gait and balance impairments, and use of psychoactive medications. The risk of falling increases with the number of risk factors present (see Sidebar: Risk Factors for Falls). One study showed that a patient with 4 risk factors has a 78% chance of falling.⁴

Screening for Falls

The most important first step that clinicians can take in preventing falls is to ask about history of falls. In 2010, the American and British geriatrics societies released updated clinical practice guidelines for fall prevention in older adults. The guidelines state that all patients age 65 years or older should be asked yearly about previous falls.⁵ Patients who report a fall or gait and balance difficulties should undergo an in-office assessment such as the Timed Up and Go test (Figure 1).

Timed Up and Go Test

This is a quick and easy test that can be performed by a trained health care team member in ambulatory care settings within a few minutes. The patient should wear regular footwear, use their usual walking aid if needed, and start by sitting back in a chair with armrests. The patient is timed while s/he rises from the chair, walks three meters, turns around, walks back to the chair, and sits back down. Postural stability, gait, stride length, sway, and steppage should be observed. Kaiser Permanente uses the operational value of 14 seconds or less. (The normal value is 10 seconds or less; and 20 seconds or more is considered abnormal.) If the result of the

Screening for Falls
- Ask about a fall history every year.
- If a patient reports a fall or gait and balance problems, perform an in-office gait evaluation such as the Timed Up and Go test.

Timed Up and Go Test
- Observe postural stability, gait, stride length, sway, and staggering.
- A normal time is 14 seconds or less.

Ask the patient to:
1. rise from the chair
2. walk three meters
3. turn around
4. walk back to the chair
5. sit back down

Risk Assessment
- Ask about the patient’s history of falls, patient’s assessment of his/her functional ability, medications, and medical history.
- Perform a gait assessment, physical exam (esp. neurologic, cardiac), assessment of orthostatic vital signs, visual acuity exam, cognitive evaluation, examination of feet and footwear, and home safety evaluation.

Ambulatory Interventions
1. Exercise/physical therapy programs aimed at improving balance, gait, and strength
2. Withdrawing or minimizing use of psychoactive medications
3. Management of postural hypotension
4. Management of foot problems
5. Changes in footwear

Hospital Interventions (based on Schmid Fall Risk Assessment)
1. Appropriate reorientation strategies
2. Access to patient’s hearing aids or glasses
3. Call bell
4. Access to patient’s personal items
5. Use of patient’s walking aids
6. Frequent comfort rounds

Fall Prevention in Hospitals

Physicians and other health care team members should be aware that in hospitals, nurses perform fall prevention assessments for every patient using standardized tools. Tools for assessing risk for falls include: the Morse Fall Scale, the Hendrich II Fall Risk Model, the Briggs Risk Assessment Form, and the Conley Risk Assessment Tool, among others. Kaiser Permanente uses the Schmid Fall Risk Assessment Tool. It involves evaluation of the patient’s mobility, mention, toileting, fall history, and use of psychoactive medications. A score of three

or more indicates an increased risk for falls requiring the following interventions:
1. appropriate reorientation strategies
2. access to patient’s hearing aids or glasses
3. call bell
4. access to patient’s personal items
5. use of patient’s walking aids
6. frequent comfort rounds
7. patient and family education about fall risk
8. early and frequent mobilization
9. nonslip footwear
10. elimination of barriers to transfer or ambulation
11. minimization of use of restraints
12. use of bed alarm when necessary.

Conclusion
Given the devastating effects falls have on patients and the increased burden on family members and the health care system, screening and assessment for fall risk are paramount priorities. Screening may be easily performed in the ambulatory and hospital settings, with simple interventions producing meaningful results. Physicians should coordinate with other health care team members to provide effective multifactorial interventions to their patients (see Sidebar: Online Resources for More Information). With each fall that is prevented, the patient, their family members, the health care team, and the health care system all benefit.
