ABSTRACT

Introduction: We present a case of membranous nephropathy associated with a secondary syphilis infection in a patient with HIV.

Case Presentation: A 37-year-old white man with HIV who was receiving highly active antiretroviral therapy presented to the Emergency Department with 6 weeks of rectal pain. He had a CD3-CD4 count of 656 cells/mm³ and an undetectable viral load. On admission, he was found to have an anal ulcer, a serum creatinine of 1.4 mg/dL (baseline 0.7 to 1.0 mg/dL), elevated transaminases, positive rapid plasmin reagin, and a urine protein/creatinine ratio revealing nephrotic-range proteinuria. Renal biopsy demonstrated membranous nephropathy with features suggestive of a secondary cause. Our patient was treated with penicillin for secondary syphilis, with normalization of renal function, resolution of the nephrotic syndrome, and improvement of his elevated transaminases.

Discussion: This case is a reminder that patients with HIV are not infrequently coinfected with Treponema pallidum and that secondary syphilis can have systemic manifestations, including elevated transaminases and nephrotic syndrome. Prompt diagnosis and treatment will result in resolution of these problems.

INTRODUCTION

Syphilis, as a disease entity, became widely known in the Western world during the Renaissance, when large outbreaks occurred that rapidly spread throughout Europe and Asia. The etiologic agent, Treponema pallidum, was identified in 1905, and with the development of medications, particularly of penicillin, and of serologic testing, syphilis became a relatively small public health issue. Since 2000, however, when the historically lowest incidence rates of syphilis in the US were observed, rates have doubled from 2.1 cases/100,000 population in 2000 to 5.3 cases/100,000 in 2013. The largest increase in incidence is seen among African American patients with high viral loads and low CD4 counts, nephrotic syndrome in patients with HIV may be caused by any number of glomerular pathologies, including immune complex glomerulonephritis, minimal change disease, and immunoglobulin A (IgA) nephropathy, among others. Thus, it would be a mistake to assume that all nephrotic syndromes presenting in an HIV-positive patient is necessarily caused by HIVAN. This is particularly true if the patient is coinfected with either syphilis, hepatitis B, or hepatitis C, each of which may cause other distinct glomerular diseases.

The following case serves as a reminder that nephrotic syndrome in a patient with HIV may not necessarily be caused by the HIV.

CASE PRESENTATION

Presenting Concerns

A 37-year-old white man with a medical history of HIV who was receiving highly active antiretroviral therapy presented to the Emergency Department with 6 weeks of rectal pain. He had been evaluated both in the Emergency Department and the urgent care clinic several times before his admission. Initially, his symptoms were thought to be caused by unprotected anal intercourse exacerbated by hard bowel movements. Seven days before his admission, the patient presented to the urgent care clinic with persistent rectal pain and subjective fevers. Examination revealed a 1-cm indurated anal lesion for which he received oral cephalexin. A biopsy of the lesion was performed. He received intravenous metronidazole before the biopsy and subsequently received trimethoprim/sulfamethoxazole when an intraoperative wound culture returned Enterococcus, Pseudomonas aeruginosa, and Bacteroides fragilis. On the day of admission, he returned to the Emergency Department with reports of nausea, vomiting, dark urine, and nonbloody status. In 2010, Horberg et al examined the Kaiser Permanente Northern California patient population and reported that the adjusted incidence rate ratio on syphilis infection in HIV vs non-HIV-infected individuals was 86.0, and that this ratio increased with time. Nephrotic syndrome is well known to be associated with HIV infection. Although the disease entity termed HIV-associated nephropathy (HIVAN), which is characterized by collapsing focal and segmental glomerulosclerosis and acute interstitial nephritis with microcystic tubular dilatation, is predominantly seen among African American patients with high viral loads and low CD4 counts, nephrotic syndrome in patients with HIV may be caused by any number of glomerular pathologies, including immune complex glomerulonephritis, minimal change disease, and immunoglobulin A (IgA) nephropathy, among others. Thus, it would be a mistake to assume that all nephrotic syndromes presenting in an HIV-positive patient is necessarily caused by HIVAN. This is particularly true if the patient is coinfected with either syphilis, hepatitis B, or hepatitis C, each of which may cause other distinct glomerular diseases.

Secondary Syphilis Associated with Membranous Nephropathy and Acute Hepatitis in a Patient with HIV: A Case Report

His rectal examination revealed ulceration at the posterolateral external anal sphincter, which was tender to palpation. Initial laboratory analysis revealed white blood cell count of $7.2 \times 10^3$/mL, hemoglobin 12.9 g/dL, mean corpuscular volume 91.5 fL, platelet 451 x 10$^3$/L, sodium 132 mEq/L, potassium 3.8 mEq/L, chloride 99 mEq/L, bicarbonate 27 mEq/L, blood urea nitrogen 17 mg/dL, and creatinine of 1.4 mg/dL. His baseline creatinine the previous year was 0.7 mg/dL to 1.0 mg/dL. Other laboratory test results included aspartate aminotransferase 221 U/L, alanine aminotransferase 255 U/L, total bilirubin 1.1 mg/dL, alkaline phosphatase 881 U/L, gamma-glutamyl transpeptidase 920 U/L, and lipase 26 U/L. Serum total protein was 4.6 g/dL and albumin was 1.1 g/dL. Prothrombin time international normalized ratio was 1.0. Both C3 and C4 complement factors were normal, as was rheumatoid factor and antinuclear antibody. Urinalysis revealed a specific gravity of > 1.050 and no leukocyte esterase or nitrite; urine protein was > 600 mg/dL, urine hemoglobin 0.20 mg/dL, urobilinogen 4.0 mg/dL, and urine bilirubin 6.0 mg/dL. Urine microscopy demonstrated urine white blood cell count > 25/high-power field, urine red blood cell 4 to 10/high-power field, and 5 to 10 hyaline casts, with 0 to 2 granular casts/low-power field. Urine culture was negative. Hansel's stain of the urine demonstrated no urinary eosinophils. Urine electrolytes yielded a urine sodium 37 mEq/L, urine potassium 92 mEq/L, urine chloride 45 mEq/L, and urine creatinine > 400 mg/dL. The urinary protein/creatinine ratio was 8.2 g/g. Urine was negative for detectable acetaminophen or salicylates.

**Therapeutic Intervention and Treatment**

Our patient presented with several medical issues that included elevated transaminases, acute kidney injury, nephrotic range proteinuria, and rectal ulceration. He received intravenous fluid hydration for presumed prerenal azotemia. Trimethoprim/sulfamethoxazole was continued. Abdominal ultrasound did not find signs of biliary obstruction or cholecystitis but did find bilateral echogenic kidneys without hydronephrosis. Antimitochondrial

![Figure 1. Renal biopsy by light microscopy. A) periodic acid-Schiff stain and B) Jones silver stain, showing mild acute tubular necrosis and mild arterial and arteriolar nephrosclerosis.](image)

![Figure 2. Renal biopsy by immunofluorescence microscopy, showing positive staining for immunoglobulin G, immunoglobulin M, C3, C1q, and kappa and lambda light chains in the capillary walls and mesangial regions.](image)
and antismooth-muscle antibodies were negative; ceruloplasmin and iron saturation were normal. Treponemal enzyme immunoassay antibody was positive, and rapid plasmin reagin was 1:16. His rapid plasmin reagin 3 months before admission was negative although his treponemal antibody was positive, confirming past infection. Hepatitis B surface antigen, core antibody, and surface antibody, and hepatitis C antibody were negative; however, hepatitis A immunoglobulin M (IgM) was positive. Herpes simplex viral culture of the anal lesion was negative. The anal ulcer biopsy revealed lymphoplasmacytoid cell proliferation without evidence of clonality or lymphoma. On hospital day 2, the patient’s serum creatinine rose to 1.58 mg/dL. The patient underwent a percutaneous renal biopsy for acute kidney injury and nephrotic syndrome. The kidney biopsy demonstrated mild acute tubular necrosis, mild arterial and arteriolar nephrosclerosis, and findings consistent with early secondary membranous nephropathy.

Pathology

Figures 1 to 3 demonstrate the results of the renal biopsy. By light microscopy (Figures 1A and 1B), there were 14 glomeruli in the biopsy specimen. All were normal in appearance. There were no crescents or segments of sclerosis. Mild acute tubular necrosis and mild arterial and arteriolar nephrosclerosis were observed. Immunofluorescence microscopy, however, demonstrated positive staining for immunoglobulin G (IgG) (4+), IgM (1–2+), C3 (3–4+), C1q (3+), and both kappa and lambda light chains (2–3+) in the capillary walls in a granular pattern and in mesangial regions. Strong granular capillary wall and mesangial staining for IgG is illustrated in Figure 2. By electron microscopy, small electron-dense deposits were identified in subepithelial and paramesangial regions (Figure 3). Podocyte foot processes were extensively effaced, and tubuloreticular inclusions were not identified.

Follow-up and Outcomes

Benzathine penicillin 2,400,000 IU once per week for 3 weeks was started for treatment of secondary syphilis. Nephrotic syndrome resolved. Follow-up laboratory tests 6 weeks after

starting penicillin therapy demonstrated a serum creatinine of 0.88 mg/dL, serum albumin 3.8 mg/dL, alanine aminotransferase 50 U/L, alkaline phosphatase 96 U/L, urine protein/creatinine ratio of < 0.15 mg/mg, and normal urinalysis. See Table 1 for a timeline of the patient’s case.

## DISCUSSION

Membranous nephropathy is among the most common diagnoses for adults with nephrotic syndrome in the general population and accounts for approximately 20% of cases of nephrotic syndrome. Histologically, membranous nephropathy is characterized by diffuse thickening of the glomerular basement membrane with immune complex deposits located in the subepithelial space, and the absence of significant inflammatory or proliferative changes. Membranous nephropathy can be either idiopathic or secondary to an underlying cause, such as solid malignant tumors, medications (eg, penicillamine, gold, nonsteroidal anti-inflammatory drugs), autoimmune diseases (eg, lupus, rheumatoid arthritis, mixed connective tissue disease), or infections (eg, hepatitis B, hepatitis C). In our case, the renal biopsy confirmed a diagnosis of early membranous nephropathy. Although the glomeruli in early membranous nephropathy may look completely normal under light microscopy, as it did in our case, the diagnosis of membranous nephropathy was confirmed by further examination of the specimen using both immunofluorescence and electron microscopy. Moreover, in our case, the immuno-fluorescence pattern and the presence of both subepithelial and mesangial immune complex deposits suggested that membranous nephropathy was secondary to an underlying condition, which we presumed to be syphilis.

Renal manifestations of syphilis are varied and include not only membranous nephropathy, but also a host of other glomerular and non-glomerular conditions (see the Sidebar: Renal Manifestations of Syphilis). Membranous nephropathy is the most common glomerular lesion seen with syphilis patients. Circulating immune complexes have been seen among patients with secondary syphilis, and immune complexes containing antitreponemal antibodies have been eluted from renal biopsy specimens. As opposed to idiopathic membranous nephropathy, where IgG and C3 staining are typically seen by immunofluorescence studies on renal biopsies, membranous nephropathy secondary to syphilis typically has staining not only for IgG and...
C3, but also occasionally with IgA, IgM, and C1q (“full house pattern”), which, with the exception of IgA staining, were seen in our case. At the time of this case presentation, immunostaining for phospholipase A2 receptor, frequently positive in primary, as opposed to secondary, membranous nephropathy, was not yet available in our facility. Our patient’s rapid clinical response to antitreponemal treatment also speaks in favor of syphilis as being the underlying cause of his membranous nephropathy.

Membranous nephropathy has also been seen in patients infected with HIV. Although the predominant glomerular lesion seen in necrotic HIV-infected patients is collapsing focal and segmental glomerulosclerosis with interstitial inflammation and tubular microcystic changes, also known as HIVAN, other immune complex glomerulonephritides have been reported in HIV-infected patients, including membranous nephropathy. In a study of patients with HIV who underwent renal biopsies, those patients who had non–HIVAN renal disease had a slower rate of progression to renal replacement therapy than did those patients with HIVAN. Moreover, in contrast to those with HIVAN, patients with non–HIVAN renal disease had a clinical course that was not significantly affected by intensification of antiviral therapy or the absence of a detectable viral load.

The treatment of HIV-associated membranous nephropathy remains uncertain. There is one case report of a patient with HIV-associated membranous nephropathy who responded dramatically to prednisone and another report of a patient who responded to intensification of antiviral therapy. In our case, although we cannot rule out HIV-associated membranous nephropathy, our patient’s rapid response to antibiotic therapy and the absence of detectable glomerular endothelial tubulo-vascular structures, which is frequently seen in HIV-associated renal disease, speak against HIV as playing a major role in our patient’s nephrotic syndrome.

Syphilis has also been associated with acute hepatitis particularly among HIV-infected patients. Although our patient had only moderately elevated transaminases without jaundice or clinical signs or symptoms of acute hepatitis, florid acute hepatitis with jaundice caused by syphilis has been reported, which resolved completely with antimicrobial therapy.

Liver biopsies have demonstrated periportal hepatocyte necrosis and pericholangiolar inflammation. As such, serum alkaline phosphatase is typically elevated out of proportion to either bilirubin or transaminase levels, as it was in our patient. Interestingly, primary syphilitic proctitis, as was presumably seen in our patient, has been associated with liver involvement, perhaps because of their common venous drainage. Our patient also had a detectable IgM against hepatitis A virus. The prolonged presence of antihepatitis A virus IgM following infection has been reported and indeed, false positive antihepatitis A virus IgM, confirmed by the absence of detectable viral RNA, has also been seen. Our patient’s clinical course with rapid resolution after treatment was not consistent with an acute hepatitis A infection.

Our patient was also taking medications that could have affected his renal function. Tenofovir is well known to have nephrotoxic effects and may present with evidence of proximal tubular dysfunction (ie, glycosuria in the absence of hyperglycemia, phosphaturia, amino aciduria, renal tubular acidosis—termed Fanconi syndrome) and proteinuria. Sulfa antibiotics are frequently implicated in cases of acute interstitial nephritis. Sulfadiazine, a sulfa antibiotic used in toxoplasmosis, is sparingly soluble and has been associated with crystal-induced acute renal failure. Moreover, sulfamethoxazole, similar to cimetidine, inhibits the tubular secretion of creatinine, resulting in an elevated serum level without an effect on the actual glomerular filtration rate. Finally, synthetic marijuana use has been associated with cases of acute kidney injury, presumably caused by acute tubular necrosis.

CONCLUSION

HIV-infected patients are frequently coinfected with other pathogens, such as syphilis, hepatitis B, and/or hepatitis C. Although similar cases have been reported, our recent case serves as a reminder that syphilis, the “great mimicker,” is commonly seen in patients with HIV and can lead to disease states such as nephrotic syndrome and hepatitis. Prompt diagnosis and treatment is essential to prevent morbidity and mortality.

Secondary Syphilis Associated with Membranous Nephropathy and Acute Hepatitis in a Patient with HIV: A Case Report

---

A Disease of an Unusual Nature

A disease of an unusual nature has invaded Italy and many other regions. In the beginning pustules are on the private parts, soon on the whole body … Moreover to this disease the physicians of our time do not yet give a name, but is called by the common name of French disease, as if this contagion were imported from France into Italy or because Italy was invaded at the same time both by the disease itself and the armies of the French.

— Niccolò Leoniceno, 1428-1524, Italian physician and humanist
