ABSTRACT

Introduction: Secure messaging is a platform for email communication between patients and their physicians. Although patient-generated emails are associated with increased use of clinical services, greater member retention, and improved quality of care, secure messaging has a marked impact on primary care physicians' workload.

Objective: To understand how the email topic and volume vary by demographics and clinical factors among members of a managed care organization.

Methods: We analyzed all secure messages sent to primary care departments by adult members of Kaiser Permanente Southern California (KPSC) in 2017.

Results: Members with a higher volume of office visits and telephone appointment visits generated a higher volume of emails to primary care physician. Members with a Centers of Medicare and Medicaid Services Hierarchical Condition Category diagnosis history sent 3 times as many emails as those without such a diagnosis history. Women accounted for nearly two-thirds of emails despite making up only half of the KPSC member population. Less than one-fourth (21.4%) of members sent 2 million total emails to their physician. Medical advice was the most common reason for sending secure messages (24.7%) in a sample studied (n = 2397).

Discussion: These findings confirm the need for additional research to more accurately quantify the additional burden from secure message utilization on primary care physicians. Knowing the factors associated with secure messaging usage and message content could assist in building more efficient staffing models and creating more efficient routing that matches the message content with a physician's scope of practice.

INTRODUCTION

Secure messaging is a protected electronic communication service between patients and physicians. Known for its ability to foster physician–patient relationships, secure email has become a ubiquitous communication tool in health care settings. Studies have shown that patient satisfaction has generally increased since adopting secure messaging in family medicine, with satisfaction scores higher on questions related to “ease of communicating with the physician” and “understanding of diagnosis/treatment plan.” Some organizations initially adopted secure messaging as a way to address low-acuity medical issues, assuming this might reduce unnecessary telephone or in-person office visits. Others have targeted young and healthy patients in an early attempt to increase use of secure messaging, assuming the millennial population is more likely to use this virtual service than the older population. The rapid adoption of secure messaging has furthered the focus on and improved the quality of patient-centered care, a pillar of Kaiser Permanente’s (KP) care delivery system.

KP’s secure messaging system was implemented in 2005, first beginning with the KP Hawaii Region. Secure messaging is facilitated through KP’s member portal (https://kp.org), which is integrated with KP’s electronic health record, HealthConnect. HealthConnect represents KP’s implementation of the Epic suite of software (Epic Systems Corp, Verona, WI). To access the member portal, patients are required to register for a kp.org account and be authenticated users. In the first quarter of 2017, more than 67% KP Southern California (KPSC) members were registered on the member portal, an 8.3% growth from the prior year. In the fourth quarter of that same year, 23.1% of all portal-registered members in KPSC sent 1 or more secure email messages to their physicians; an average of 1272 emails were sent per 1000 registered members in a year. When the 3.6% membership increase from the previous year is factored in, 2017 saw an 11% increase in secure messages from 2016, with a total of 5,807,833 secure messages sent. Secure messaging is now a common form of physician–patient interaction through which care is provided and common concerns are addressed by the care team.

This study analyzed all adult-generated secure messages in the KPSC Region. The purpose of this study was to better understand the usage of secure messaging between KPSC members and primary care departments. This was accomplished by 1) comparing the use of secure messaging against the utilization of office visits and telephone appointment visits (TAVs) in primary care, 2) examining the demographic characteristics of patients who use KP’s secure messaging platform, and 3) investigating the content of secure messages that KP members sent to their primary care physicians (PCPs).

METHODS

Study Design and Population

After obtaining KP institutional review board approval, we conducted a retrospective study analyzing patient demographic data (eg, age, sex), clinical factors (eg, Health Plan type, time between a sent message and nearest completed office visit), and primary care utilization data (eg, encounter volume). All data examined in this study pertain to the utilization of primary care services in Southern California, by adult KPSC members from January 2017 to December 2017. Primary care included both family medicine and internal medicine specialties.

Keywords: family medicine, patient-generated emails, primary care email topics, physician-patient communication, physician-patient relationship, secure messaging
Data from the Pediatrics and Obstetrics/Gynecology Departments were not included in this study. At KP, members seeking care for primary care services have several options. For the purposes of this study, we focused on 3 main primary care services: Office visits, TAVs, and secure messaging. To quantify the utilization of these modalities, we counted instances of the following primary care services for each individual who held a KP membership in 2017 (47.3 million KP members):

1. Office visits in 2017 (n = 4,908,596) to primary care departments by adult KPSC members
2. Telephone appointment visits (n = 1,185,390) with primary care departments by adult KPSC members in 2017

### Table 1. Primary topic categories

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Medical advice</td>
<td>Physical or mental health problem or concern not coded as a medication issue or test issue. My right shoulder has been extremely sore for more than a month. I can’t lift my right arm up and to the side without great pain. This has been over a month and getting worse.</td>
<td></td>
</tr>
<tr>
<td>New or change in medication request</td>
<td>Request for a new medication or a change of current medication. My current medication isn’t working for me anymore but my systolic blood pressure is off the charts.</td>
<td></td>
</tr>
<tr>
<td>Medication renewal or refill</td>
<td>Measure for refill or renewal of a medication or medication supply. Please renew my prescription for oxycodone HCL 5 mg tablet. Please have pharmacy mail (it) to me.</td>
<td></td>
</tr>
<tr>
<td>Medication issue/ question</td>
<td>Medication issue or supply that is not a refill or new request or a problem with renewing the medication in mail (eg, questions about dose or side effects). I’m sending a list of vitamins and supplements I take. Please have the doctor make sure they are okay to take and don’t count/calculate what I’ve taken for my Parkinson’s (disease).</td>
<td></td>
</tr>
<tr>
<td>Imaging request</td>
<td>Request for imaging/test. ‘I’ve been having terrible headaches and I want a CT scan to see what the problem is.’</td>
<td></td>
</tr>
<tr>
<td>Imaging result</td>
<td>Request for discussion of imaging results. ‘Hello, I got the ultrasound [scan result] test last week and I want to know what are the next steps to take?’</td>
<td></td>
</tr>
<tr>
<td>Lab request</td>
<td>Request for lab test. ‘I need some bloodwork done.’</td>
<td></td>
</tr>
<tr>
<td>Lab/test issuance request</td>
<td>Patient questions about imaging, choosing among imaging options, or a particular imaging procedure is important, preparing for a scan/imaging procedure. ‘I want you to get your lab work done before I see you!’</td>
<td></td>
</tr>
<tr>
<td>Lab/test results</td>
<td>Request for or discussion of test results. ‘Thanks for sending me the test results, I still have a question for the doctor about the numbers that you gave me.’</td>
<td></td>
</tr>
<tr>
<td>Surgery or procedure issuance question</td>
<td>Patient questions about a surgery or procedure. ‘Good morning, I am still having a lot of pain in my knee. The injections did not seem to help. But I heard the second time around usually helps a lot more. So, was I wondering if I can get another injection in my knee?’</td>
<td></td>
</tr>
<tr>
<td>PHI informing</td>
<td>Patient sharing information with no additional discussion that does not fit other category (eg, information about non-VKH care or test result). ‘Just to keep you posted. ENbG done yesterday. Bloodwork and urine done this AM.’</td>
<td></td>
</tr>
<tr>
<td>Scheduling</td>
<td>Schedule an appointment, test, or procedure. ‘I would like to set up an appointment for a physical.’</td>
<td></td>
</tr>
<tr>
<td>Referral</td>
<td>Request to refer to a specialist. ‘I would like to be referred to REVIVE to help me with some weight loss. I also think it’s the battery, but I don’t know how to fix it. Tell me how or what to do.’</td>
<td></td>
</tr>
<tr>
<td>Note request</td>
<td>Request to refer to a specialist. ‘I’m supposed to go on vacation the week but I’m still sick to fly. Can you write me a note for my travel insurance?’</td>
<td></td>
</tr>
<tr>
<td>Administrative issues</td>
<td>Administrative issues other than appointment scheduling. ‘I didn’t receive my medication in the mail.’</td>
<td></td>
</tr>
<tr>
<td>Lifes issue</td>
<td>Any concernable issues that are not strictly biomedical and are about the patient’s life context. ‘We’re having lots of changes with my mom. Hospice people are coming here now but they’re talking about putting her in a nursing home. They say they can help her all the time.’</td>
<td></td>
</tr>
<tr>
<td>Callback request</td>
<td>Simple callback request. ‘Please call me at 900-999-9999 when you get the chance.’</td>
<td></td>
</tr>
<tr>
<td>Thanks</td>
<td>Expressing appreciation. ‘I do want to take a minute to thank you for your help. It is a different world going through a pain-free day. You have been kind and caring and I do really appreciate it!’</td>
<td></td>
</tr>
<tr>
<td>Complaint</td>
<td>Complaining about care, services, KP, etc. ‘First and foremost … and I would think you would be aware of this by now, [patient first name] is NOT my Dad … he’s my husband.’</td>
<td></td>
</tr>
<tr>
<td>Other</td>
<td>Content not captured by the above categories. ‘Both of my gifted kids are making reading 9-0-5 when trying to get a reading. I think it’s the battery, but I don’t know how to fix it. Tell me how or what to do.’</td>

### Figure 1: Effect of clinical factors on secure messaging. Coefficients indicate association of each factor with the reference patient (see text). *Includes regression coefficients of greatest magnitude. TAV = telephone appointment visit.

### RESULTS

Utilization of Primary Care Services

As shown in Figure 1, the number of completed primary care office visits by a member was most strongly associated with a member sending a greater number of messages to the primary care department. The number of TAVs was the second strongest factor. Other factors associated with a member sending more secure messages included being a Medicaid member, being a woman, and having a prior CMS HCC diagnosis. Because this regression looks at each variable individually, this study’s findings show that having an office visit was more indicative of sending a secure message than being a Medicare member or having a chronic disease. Conversely, being a KP-Medicaid member and self-identifying as black and/or Hispanic were factors associated with fewer secure messages sent.

Average counts of office visits utilized were similar between racial groups, but propensities for secure messaging varied widely (Table 2). Though there was only a small difference between average numbers of office visits between black, Hispanic, and white members, members who self-identified as black and/or Hispanic utilized office visits in lower numbers than other racial groups.

Table 5 also shows the average counts for members who did not have any office visits, TAVs, or secure messages sent.

As seen in Table 3, members who had at least 1 office visit had, on average, 3.63 TAVs. Members who initiated a secure message thread initiated nearly 3 messages on average.

Our study findings reveal that members with a higher utilization of different primary care services, the biggest difference in utilization between sexes was seen in TAVs, with female members accounting for 65% of TAV encounters.

In Figure 3, the largest volume of messages is highlighted, detailing that 7.69% of messages sent by adult members to primary care departments were sent within 3 days of a PCP office visit. Another 14.85% of messages were sent within 3 days of a PCP office visit, and 37.3% of messages were sent within 7 days of a PCP office visit.

Utilization by Chronic Condition Diagnosis

OF KPSC members, 42.9% had a chronic condition, yet this population accounted for two-thirds of primary care service utilization. Those KP members with a chronic condition used TAVs and secure messaging more than in-person office visits.

In Table 4, patients with a chronic condition diagnosis history sent more than 3 times as many secure messages to their PCP and had 2 times as many office visits compared with patients without any chronic condition diagnosis.

Utilization by Sex

Approximately half of KPSC members (51.7%) in 2017 were women, but female members accounted for almost two-thirds of primary care utilization. On average, 5 of 8 messages sent to a PCP were sent by women. In a comparison of the 3 different primary care services, the biggest difference in utilization between sexes was seen in TAVs, with female members accounting for 65% of TAV encounters.

Correlation between Secure Messaging and Office Visits/TAVs

Approximately half of KPSC members (51.7%) in 2017 were women, but female members accounted for almost two-thirds of primary care utilization. On average, 5 of 8 messages sent to a PCP were sent by women. In a comparison of the 3 different primary care services, the biggest difference in utilization between sexes was seen in TAVs, with female members accounting for 65% of TAV encounters.

Approximately half of KPSC members (51.7%) in 2017 were women, but female members accounted for almost two-thirds of primary care utilization. On average, 5 of 8 messages sent to a PCP were sent by women. In a comparison of the 3 different primary care services, the biggest difference in utilization between sexes was seen in TAVs, with female members accounting for 65% of TAV encounters.

Utilization of Secure Messaging to Primary Care Departments

KPSC, our PCPs often prompt patients at the end of their office visits to email them if they have any further questions. Whereas our study results suggest an association between the volume of secure messaging and office visits, other studies have shown that the relationship between secure messaging, office visits, and TAVs is complex. Some studies have shown that messaging can replace the number of office visits or TAVs; other studies have suggested that secure messaging either increases or does not alter the utilization of office visits or telephone calls.4,12-22 Further studies must be done to confirm these correlations.

Studies have found that patients with certain demographic backgrounds used care services overall more than others did.3,4,12 Our study findings confirm previous research by demonstrating that certain patient variables, such as being a woman, being white, having a chronic condition, and being older, contribute to higher secure messaging utilization. Moreover, results of this study reveal the magnitude at which certain clinical and patient demographic factors affect secure message utilization. A member having a CMS HCC diagnosis history may send 3 times as many emails to primary care than a member without an HCC diagnosis history. Women also account for almost two-thirds of secure messaging to primary care departments excluding Obstetrics/Gynecology. Because of this exclusion, our results likely underestimate the message gap between sexes. In a comparison of the 3 different primary care services, the biggest difference in utilization between sexes was seen in virtual services, with female members using 65% of TAVs, 62-49% of secure messaging encounters.

Many studies have researched the heavy adoption of secure messaging in outpatient medicine and Obstetrics/Gynecology.12-14 Data shows that the adoption of the secure messaging platform is not yet widespread. Nearly 25% of the KPSC member population used the secure messaging platform in 2017. This group sent approximately 2.3 million messages in 2017. This finding can also be interpreted as more than 73% of KPSC members have yet to adopt secure messaging. Past KP trends data suggest, however, that the use of secure messaging increases each year.26 The primary care team needs to be well positioned to account for the increased general adoption of secure messaging.

Our study adds to existing research by looking at message topics to primary care departments. Consistent with other studies, medical advice is ranked as one of the top message topics that members are inquiring about.12,22 The top 6 message topics following medical advice are very similar to the message topic study conducted at Veterans Affairs medical centers,12 with a slight difference in topic ranks. The variation could be caused by the small sample size and difference in the service population. Knowing what types of messages patients are sending will help when building, prioritizing, or updating routing protocols.

Practical Applications

Today, drivers of secure message utilization are not commonly considered in certain aspects of the secure message management system in primary care settings. Knowing the factors associated with secure messaging utilization and the message content could assist in the following: 1) building more efficient staffing models; 2) creating more efficient routing that matches the secure message content with maximum scope of practice allowed for nurses, pharmacists, and advanced practice physicians; and 3) using message volume as a weighted factor that influences a PCP’s panel ceiling, or cap.

Routing Secure Messages

Staffing Models

Our analysis suggests that certain populations tend to send a larger number of secure messages and therefore produce additional virtual work for physicians. The factors in these populations should be considered by health systems when developing staffing and resource allocation protocols to address this imbalance. For example, if a physician is projected to have a heavier secure message workload based on his/her panel, nurses experienced with handling secure messaging can be assigned to assist.

Understanding what patients are messaging about can aid in designing a more efficient secure messaging model to route and prioritize messages, stratifying them for the appropriate recipient.
For example, if messages about medications have a high volume, there may be value in routing messages about medication to pharmacists directly, bypassing the primary care team.

Optimized Panel Calculation

To account for workload owing to messaging volumes, our research findings suggest that some patient variables should be considered when health systems calculate PCP panel sizes. PCPs whose panels contain white, Medicare-eligible women with a chronic condition likely have a heavier workload because of the increased volume of secure messages they receive from these patient populations.

Limitations

This study has several limitations. First, our study included secure messages through https://kp.org only to the Family Medicine and Internal Medicine departments, excluding the Pediatrics and Obstetrics/Gynecology Departments. Our analysis did not include any messages to specialty departments. Second, we examined data from only a single KP Region, KPSC. Our study does not include messaging, office visit, and TAV data trends from other KP Regions. Studies have found that the relationship between secure messaging, office visits, and TAVs is complex. Some study findings have shown that messaging can replace the number of office visits or TAVs; other studies have suggested that secure messaging either increases or does not alter the utilization of office visits or telephone calls.12-15 Therefore, our study, being an observational study, cannot claim whether messaging drives other forms of care or vice versa. To make such a claim about causality, we would need a randomized controlled trial. The results in this article speak only to associations.

Last, it is important to note that the total number of secure messages sampled in this study reflects only the 21.4% of KPSC members who used secure messaging and does not reflect the population as a whole. As more and more members adopt the service, further studies are needed to determine if the observations from this study stay consistent.

CONCLUSION

This study examined several factors that were often associated with utilization of secure messaging, ranging from having an office visit to having a chronic condition. Factors most strongly associated with increased utilization of secure messaging were the numbers of primary care office visits and TAVs. Demographic factors associated with secure messaging utilization included age, sex, HCC diagnosis history, and Health Plan type. Being white, female, and older and having a Medicare Health Plan type and a previous HCC diagnosis were associated with higher utilization of secure messages. The findings of this study reveal the magnitudes and possible five factors on secure message utilization and challenge many existing assumptions around secure messaging.
